The diameter of the piston, and the inside diameter of the cylinder, is called the bore - B. So the area A of the head of the piston is  $\pi (3.14159)$  times the diameter squared divided by four.  $A = \pi * B^2 / 4$  The volume swept out during any complete stroke is the piston area times the stroke:  $V = \pi * S * B^2 / 4$

In a reciprocating piston engine, the stroke ratio, defined by either bore/stroke ratio or stroke/bore ratio, is a term to describe the ratio between cylinder bore diameter and piston stroke. This can be used for either an internal combustion engine, where the fuel is burned within the cylinders of the engine, or external combustion engine, such as a steam engine, where the combustion of the fuel takes place outside the working cylinders of the engine. Engine friction is affected by the stroke-to-bore ratio because of two competing effects: crankshaft bearing friction and power-cylinder friction. As the stroke-to-bore ratio decreases, the bearing friction increases because the larger piston area transfers larger forces to the crankshaft bearings.
